# Search and matching models

## Search and matching models

- ▶ Extremely popular these days (and for many years now)
- ▶ Inspired by work of Diamond, Mortensen and Pissarides
- ▶ Apart from some recent examples (e.g. our companion paper and the references therein), these models do not include a saving mechanism

## Our setup

- ▶ Pissarides textbook model (without Nash-bargaining) extended for a consumption-saving mechanism
- ▶ Process of matching and separation is augmented to allow for self-insurance of workers
- ▶ We describe distributional prediction for labour market status and wealth using Fokker-Planck equations in a companion paper

# Search and matching models

## Search and matching models

- ▶ Extremely popular these days (and for many years now)
- ▶ Inspired by work of Diamond, Mortensen and Pissarides
- ▶ Apart from some recent examples (e.g. our companion paper and the references therein), these models do not include a saving mechanism

## Our setup

- ▶ Pissarides textbook model (without Nash-bargaining) extended for a consumption-saving mechanism
- ▶ Process of matching and separation is augmented to allow for self-insurance of workers
- ▶ We describe distributional prediction for labour market status and wealth using Fokker-Planck equations in a companion paper

# The model

## Matching on the labour market

- ▶ Transitions between states  $z \in \{w, b\}$  with (state-dependent) matching rate  $\mu$  and separation rate  $s$
- ▶ Wage  $w$  and benefits  $b$  are exogenous (in this stability paper, not in companion paper)
- ▶ Representation for maximisation problem as a stochastic differential equation with two Poisson processes

$$dz(t) = \Delta [dq_\mu - dq_s], \quad \Delta \equiv w - b$$

- ▶ Corresponds to cont. time Markov chain

## Budget constraint of an individual

$$da(t) = \{ra(t) + z(t) - c(t)\} dt$$

- ▶ Interest rate on wealth  $r$ , consumption  $c(t)$

# The model

## Matching on the labour market

- ▶ Transitions between states  $z \in \{w, b\}$  with (state-dependent) matching rate  $\mu$  and separation rate  $s$
- ▶ Wage  $w$  and benefits  $b$  are exogenous (in this stability paper, not in companion paper)
- ▶ Representation for maximisation problem as a stochastic differential equation with two Poisson processes

$$dz(t) = \Delta [dq_\mu - dq_s], \quad \Delta \equiv w - b$$

- ▶ Corresponds to cont. time Markov chain

## Budget constraint of an individual

$$da(t) = \{ra(t) + z(t) - c(t)\} dt$$

- ▶ Interest rate on wealth  $r$ , consumption  $c(t)$

# Optimality

## Utility functions

- ▶ Intertemporal

$$U(t) = E_t \int_t^{\infty} e^{-\rho[\tau-t]} u(c(\tau)) d\tau$$

- ▶ CRRA instantaneous utility function

$$u(c(\tau)) = \frac{c(\tau)^{1-\sigma} - 1}{1-\sigma}, \quad \sigma > 0$$

## Optimality condition

- ▶ Generalized Keynes-Ramsey rule
- ▶ Represented for this paper by policy function  $c(a(t), z(t))$

# Optimality

## Utility functions

- ▶ Intertemporal

$$U(t) = E_t \int_t^{\infty} e^{-\rho[\tau-t]} u(c(\tau)) d\tau$$

- ▶ CRRA instantaneous utility function

$$u(c(\tau)) = \frac{c(\tau)^{1-\sigma} - 1}{1-\sigma}, \quad \sigma > 0$$

## Optimality condition

- ▶ Generalized Keynes-Ramsey rule
- ▶ Represented for this paper by policy function  $c(a(t), z(t))$

# Dynamics

## System to be understood

- ▶ Frictional labour market equation

$$dz(t) = \Delta [dq_\mu - dq_s], \quad \Delta \equiv w - b$$

- ▶ Optimal evolution of wealth

$$da(t) = \{ra(t) + z(t) - c(a(t), z(t))\} dt$$

## Different regimes

- ▶ Low interest rate  $r \leq \rho$ : bounded state space  $[-b/r, a_w^*]$  for wealth
- ▶ High interest rate  $r \geq \rho + \mu$ :  $a_t$  increasing to  $\infty$
- ▶ Intermediate case:  $a_t$  increasing to  $\infty$  when larger than a threshold value

# Dynamics

System to be understood

- ▶ Frictional labour market equation

$$dz(t) = \Delta [dq_\mu - dq_s], \quad \Delta \equiv w - b$$

- ▶ Optimal evolution of wealth

$$da(t) = \{ra(t) + z(t) - c(a(t), z(t))\} dt$$

Different regimes

- ▶ **Low interest rate**  $r \leq \rho$ : bounded state space  $[-b/r, a_w^*]$  for wealth
- ▶ High interest rate  $r \geq \rho + \mu$ :  $a_t$  increasing to  $\infty$
- ▶ Intermediate case:  $a_t$  increasing to  $\infty$  when larger than a threshold value

# Outline

- 1 Introduction
  - Search and matching models
  - Our model
- 2 Abstract stability theory in continuous time
  - Setting and methodology
  - Existence of an invariant probability measure
  - Uniqueness of invariant measures
  - Stability
- 3 Application to the model
  - Existence and stability
  - A sufficient condition for recurrence

# Setting

- ▶ State space  $(\mathbf{X}, \mathcal{B}(\mathbf{X}))$  locally compact separable metric space
- ▶  $(X_t)_{t \in [0, \infty[}$  right-continuous, time-homogeneous strong Markov process
- ▶ *Transition kernel*  $P^t(x, A) := P(X_t \in A | X_0 = x)$
- ▶ *Semi-group*  $P_t f(x) := E[f(X_t) | X_0 = x] = \int_{\mathbf{X}} f(y) P^t(x, dy).$

## Example

For the wealth-employment process  $(A_t, z_t)$  in the low-interest-regime, the state space is chosen to be  $\mathbf{X} = [-b/r, a_w^*] \times \{w, b\}$ , a compact, separable metric space.

# Setting

- ▶ State space  $(\mathbf{X}, \mathcal{B}(\mathbf{X}))$  locally compact separable metric space
- ▶  $(X_t)_{t \in [0, \infty[}$  right-continuous, time-homogeneous strong Markov process
- ▶ *Transition kernel*  $P^t(x, A) := P(X_t \in A | X_0 = x)$
- ▶ *Semi-group*  $P_t f(x) := E[f(X_t) | X_0 = x] = \int_{\mathbf{X}} f(y) P^t(x, dy).$

## Example

For the wealth-employment process  $(A_t, z_t)$  in the low-interest-regime, the state space is chosen to be  $\mathbf{X} = [-b/r, a_w^*] \times \{w, b\}$ , a compact, separable metric space.

# Methodology

There are (at least) two very different approaches:

**Functional analysis:** use the classical theory of strongly continuous semi-groups of linear operators on Banach spaces

**Probability:** analogy to discrete-time Markov chains, i.e., study the recurrence structure

- ▶ We are going to follow the probabilistic road, the semi-group  $(P_t)_{t \in [0, \infty[}$  and its infinitesimal generator will *not* be used.
- ▶ Based on a long history of results, ultimate treatment by Meyn and Tweedie and their co-authors in 90's.

# Methodology

- ▶ Based on a long history of results, ultimate treatment by Meyn and Tweedie and their co-authors in 90's.

# Outline

## Goal

- ▶ **Stability** is a rather vague concept.
- ▶ Here: ergodicity in the sense that for any initial state  $x$ ,  
 $P^t(x, \cdot) \xrightarrow{t \rightarrow \infty} \pi$  for some unique probability distribution  $\pi$ .
- ▶ No time-averaging necessary.

## Definition

A measure  $\mu$  on  $\mathbf{X}$  is called invariant, iff

$$\forall A \in \mathcal{B}(\mathbf{X}), \forall t \geq 0 : P_\mu^t(A) := \int_{\mathbf{X}} P^t(x, A) \mu(dx) = \mu(A),$$

i.e., the process  $X_t$  with law  $(X_0) = \mu$  is stationary.

# Outline

## Goal

# Existence of an invariant probability measure

- ▶ Existence of an invariant probability distribution depends on a growth condition: no mass is allowed to escape to infinity.
- ▶  $X_t$  is bounded in probability on average, iff  $\forall x \in \mathbf{X}$ ,  $\epsilon > 0$  there is a compact set  $C \subset \mathbf{X}$  s.t.

$$\liminf_{t \rightarrow \infty} \frac{1}{t} \int_0^t P^s(x, C) ds \geq 1 - \epsilon.$$

- ▶ Compactness of measures  $\frac{1}{t} \int_0^t P^s(x, C) ds$
- ▶  $X_t$  has the weak Feller property, iff for any bounded cont.  $f : \mathbf{X} \rightarrow \mathbb{R}$  and  $t > 0$ ,  $x \mapsto \int_{\mathbf{X}} f(y) P^t(x, dy)$  is continuous.

## Theorem (Beneš '68)

*If the process  $X_t$  is bounded in probability on average and has the weak Feller property, then there is an invariant probability measure.*

# Existence of an invariant probability measure

## Theorem (Beneš '68)

*If the process  $X_t$  is bounded in probability on average and has the weak Feller property, then there is an invariant **probability** measure.*

**[[SO EXISTENCE FOLLOWS FROM COMPACTNESS, AS THE ABOVE FAMILY OF MEASURES HAS SOME CONVERGENT SUBSEQUENCES. EACH LIMIT ALONG A CONVERGENT SUBSEQUENCE IS AN INVARIANT PROBABILITY MEASURE, BUT THERE CAN BE MORE THAN ONE. CONCEPTUALLY, WHY DO WE EVEN NEED WEAK FELLER? UNDERSTAND THE FOLLOWING PROOF!]]**

# Uniqueness of the invariant measure

- ▶  $X_t$  is **recurrent**, iff there is a (non-trivial)  $\sigma$ -finite measure  $\mu$  such that

$$A \in \mathcal{B}(\mathbf{X}), \mu(A) > 0 \Rightarrow \forall x \in \mathbf{X} : P(\tau_A < \infty | X_0 = x) = 1,$$

where  $\tau_A := \inf\{t \geq 0 | X_t \in A\}$ .

Theorem (Azéma, Duflo, Revuz '69)

*If the process  $X_t$  is recurrent, then there is a unique  $\sigma$ -finite invariant measure (up to constant multiples).*

Example

Let  $W_t$  be 1-dimensional Brownian motion. By recurrence, there is a unique invariant measure, whose density satisfies  $\Delta f = 0$ , implying that  $f = 1$ .

# Uniqueness of the invariant measure

- ▶  $X_t$  is recurrent, iff there is a (non-trivial)  $\sigma$ -finite measure  $\mu$  such that

$$A \in \mathcal{B}(\mathbf{X}), \mu(A) > 0 \Rightarrow \forall x \in \mathbf{X} : P(\tau_A < \infty | X_0 = x) = 1,$$

where  $\tau_A := \inf\{t \geq 0 | X_t \in A\}$ .

## Theorem (Azéma, Duflo, Revuz '69)

*If the process  $X_t$  is recurrent, then there is a unique  $\sigma$ -finite invariant measure (up to constant multiples).*

## Example

## Example

Let  $W_t$  be 1-dimensional Brownian motion. By recurrence, there is a unique invariant measure, whose density satisfies  $\Delta f = 0$ , implying that  $f = 1$ .

**[[UNDERSTAND WHY STRONG FELLER IMPLIES  
RECURRENCE/UNIQUENESS]]**

**[[UNDERSTAND WHY A-PERIODICITY NOT NECESSARY]]**

# Stability

- ▶ Stability for us means convergence  $P^t(x, \cdot) \rightarrow \pi$  for any  $x$  in **total variation**, i.e.,

$$d_{TV}(P^t(x, \cdot), \pi) := \sup \left\{ |P^t(x, A) - \pi(A)| \mid A \in \mathcal{B}(\mathbf{X}) \right\} \xrightarrow{t \rightarrow \infty} 0.$$

- ▶ Stability holds for a Harris recurrent Markov process  $X_t$  iff for some  $\Delta > 0$ , the skeleton chain  $(X_{n\Delta})_{n \in \mathbb{N}}$  is irreducible.

## Remark

*Techniques based on Lyapunov functions even allow to specify the speed of convergence. But no general way to construct good Lyapunov functions.*

# Stability

- ▶ Stability for us means convergence  $P^t(x, \cdot) \rightarrow \pi$  for any  $x$  in total variation, i.e.,

$$d_{TV}(P^t(x, \cdot), \pi) := \sup \left\{ |P^t(x, A) - \pi(A)| \mid A \in \mathcal{B}(\mathbf{X}) \right\} \xrightarrow{t \rightarrow \infty} 0.$$

  - Setting and methodology
  - Existence of an invariant probability measure
  - Uniqueness of invariant measures
  - Stability
- 3 Application to the model
  - Existence and stability
  - A sufficient condition for recurrence

# Existence and stability

- ▶ In the regimes of high and intermediate interest rates, wealth can converge to  $\infty$ .
- ▶ We concentrate on the low-interest-regime, where wealth is concentrated in a compact interval  $[-b/r, a_w^*]$ .
- ▶ By continuity of solutions of ODEs in the initial value,  $(a_t, z_t)$  is a continuous function of  $(a_0, z_0)$ , implying the weak Feller property.
- ▶ Existence of invariant probability measures.
- ▶ If  $z_0 = b$  or  $z_0 = w$  and no jump, then  $a_t \rightarrow -b/r$  or  $a_t \rightarrow a_w^*$ , respectively, implying the existence of an irreducible skeleton.
- ▶ But how to prove recurrence?

# Existence and stability

- ▶ But how to prove recurrence?

# Sufficient condition for recurrence

- ▶ Recurrence holds when transition kernel is **smoothing**.
- ▶ Diffusion case: recurrence follows under weak conditions
- ▶ Jump processes cannot smoothen as long as there is a positive probability of no jumps before  $t$

## Definition & theorem (Meyn and Tweedie '93)

$X_t$  is called a  $T$ -process if there is a Markov kernel  $T$  and a prob. measure  $\nu$  on  $[0, \infty[$  s.t.

- ▶  $\forall A \in \mathcal{B}(X) : x \mapsto T(x, A)$  is continuous
- ▶  $K_\nu(x, A) := \int_0^\infty P^t(x, A) \nu(dt) \geq T(x, A)$
- ▶  $\forall x : T(x, X) > 0.$

Any irreducible  $T$ -process, which is bounded in probability on average, is recurrent.

# Sufficient condition for recurrence

- ▶ Recurrence holds when transition kernel is smoothing.
- ▶ Diffusion case: recurrence follows under weak conditions
- ▶ Jump processes cannot smoothen as long as there is a positive probability of no jumps before  $t$

## Definition & theorem (Meyn and Tweedie '93)

$X_t$  is called a  **$T$ -process** if there is a Markov kernel  $T$  and a prob. measure  $\nu$  on  $[0, \infty[$  s.t.

- ▶  $\forall A \in \mathcal{B}(\mathbf{X}) : x \mapsto T(x, A)$  is continuous
- ▶  $K_\nu(x, A) := \int_0^\infty P^t(x, A) \nu(dt) \geq T(x, A)$
- ▶  $\forall x : T(x, \mathbf{X}) > 0$ .

Any irreducible  $T$ -process, which is bounded in probability on average, is recurrent.

# Sufficient condition for recurrence

- ▶ Recurrence holds when transition kernel is smoothing.
- ▶ Diffusion case: recurrence follows under weak conditions
- ▶ Jump processes cannot smoothen as long as there is a positive probability of no jumps before  $t$

## Definition & theorem (Meyn and Tweedie '93)

$X_t$  is called a  $T$ -process if there is a Markov kernel  $T$  and a prob. measure  $\nu$  on  $[0, \infty[$  s.t.

- ▶  $\forall A \in \mathcal{B}(\mathbf{X}) : x \mapsto T(x, A)$  is continuous
- ▶  $K_\nu(x, A) := \int_0^\infty P^t(x, A)\nu(dt) \geq T(x, A)$
- ▶  $\forall x : T(x, \mathbf{X}) > 0$ .

Any irreducible  $T$ -process, which is bounded in probability on average, is recurrent.

# The wealth-employment process is a $T$ -process

- ▶ Given  $(a_0, z_0)$ ,  $(a_t, z_t)$  is a deterministic function of the **jump-times** of  $z_t$ .
- ▶ Conditional on the number of jumps, the jump times have smooth densities.
- ▶  $(a_t, z_t)$  is not smoothing, because no jump might occur.
- ▶ If at least one jump occurs, we have smoothing properties.
- ▶ Choose  $\nu = \delta_\tau$  and

$$T((a_0, z_0), A) := P\left((a_\tau, z_\tau) \in A, \text{ one jump in } [0, \tau] \mid a_0, z_0\right).$$

- ▶ Technical condition:  $c = c(a, z)$  is  $C^1$ .
- ▶ Illustration of how  $T$ -property replaces strong Feller condition.

# The wealth-employment process is a $T$ -process

- ▶ Given  $(a_0, z_0)$ ,  $(a_t, z_t)$  is a deterministic function of the jump-times of  $z_t$ .
- ▶ Conditional on the number of jumps, the jump times have smooth densities.
- ▶  $(a_t, z_t)$  is not smoothing, because no jump might occur.
- ▶ **If** at least one jump occurs, we have smoothing properties.
- ▶ Choose  $\nu = \delta_\tau$  and

$$T((a_0, z_0), A) := P\left((a_\tau, z_\tau) \in A, \text{ one jump in } [0, \tau] \mid a_0, z_0\right).$$

- ▶ Technical condition:  $c = c(a, z)$  is  $C^1$ .
- ▶ Illustration of how  $T$ -property replaces strong Feller condition.

# The wealth-employment process is a $T$ -process

- ▶ Technical condition:  $c = c(a, z)$  is  $C^1$ .
- ▶ Illustration of how  $T$ -property replaces strong Feller condition.

# Conclusions

## Framework

- ▶ Individual maximization problem inspired by search and matching models
- ▶ Extended for consumption-saving problem
- ▶ Question: Is there a unique long-run distribution to which initial distributions converge?

## Techniques

- ▶ Markov chain-style ergodicity analysis for general, continuous time Markov processes
- ▶  $T$ -processes by Meyn and Tweedie allow to prove recurrence for a wide class of (degenerate) diffusion and jump models

## Result

- ▶ Long-run-distribution exists in our matching-saving model

# Conclusions
