Advanced Topics from Scientific Computing TU Berlin Winter 2024/25 Notebook 12 Jürgen Fuhrmann

Partial Differential Equations

Notations

Given: domain $\Omega \subset \mathbb{R}^d$ ($d = 1, 2, 3...$)

- Dot product: for $\vec{x}, \vec{y} \in \mathbb{R}^d$,
- Bounded domain $\Omega \subset \mathbb{R}^d$, with piecewise smooth boundary
- Scalar function $u:\Omega\to\mathbb{R}$
- Vector function $\vec{v} = \begin{pmatrix} v_1 \\ \vdots \\ v_d \end{pmatrix} : \Omega \to \mathbb{R}^d$
- Partial derivative $\partial_i u = \frac{\partial u}{\partial x_i}$
- Second partial derivative $\partial_{ij}u = \frac{\partial^2 u}{\partial x_i x_j}$
- *Gradient* of scalar function $u : \Omega \to \mathbb{R}$:

$$
\text{grad} = \vec{\nabla} = \begin{pmatrix} \partial_1 \\ \vdots \\ \partial_d \end{pmatrix} : u \mapsto \vec{\nabla} u = \begin{pmatrix} \partial_1 u \\ \vdots \\ \partial_d u \end{pmatrix}
$$

• *Divergence* of vector function $\vec{v} = \Omega \rightarrow \mathbb{R}^d$:

$$
\mathrm{div}=\nabla\cdot:\vec{v}=\begin{pmatrix}v_1\\ \vdots\\ v_d \end{pmatrix}\mapsto\nabla\cdot\ \vec{v}=\partial_1v_1+\dots+\partial_d v_d
$$

• Laplace operator of scalar function $u:\Omega\to\mathbb{R}$

$$
\begin{aligned} \mathrm{div}\cdot \mathrm{grad}&=\nabla\cdot\vec{\nabla}\\ &=\Delta: u\mapsto \Delta u=\partial_{11}u+\dots+\partial_{dd}u \end{aligned}
$$

Lipschitz domains

Definition: A connected open subset $\Omega \subset \mathbb{R}^d$ is called *domain*. If Ω is a bounded set, the domain is called *bounded*.

Definition:

- Let $D \subset \mathbb{R}^n$. A function $f: D \to \mathbb{R}^m$ is called *Lipschitz continuous* if there exists $s\in\mathbb{S}$ such that $||f(x)-f(y)||\leq c||x-y||$ for any $x,y\in D$
- A hypersurface in \mathbb{R}^n is a *graph* if for some **k** it can be represented on some domain $D \subset \mathbb{R}^{n-1}$ as

$$
x_k=f(x_1,\ldots,x_{k-1},x_{k+1},\ldots,x_n)
$$

$$
cusp at x = 0
$$

Divergence theorem (Gauss' theorem)

Theorem: Let $\Omega \subset \backslash \mathbf{RR}^d$ be a bounded Lipschitz domain and $\setminus \mathbf{vv} : \Omega \to \backslash \mathbf{RR}^d$ be a continuously differentiable vector function. Let $\sqrt{\text{vn}}$ be the outward normal to Ω . Then,

$$
\int_{\Omega} \nabla \cdot \langle \mathbf{v} \mathbf{v} \, d \rangle \mathbf{v} \mathbf{x} = \int_{\partial \Omega} \langle \mathbf{v} \mathbf{v} \cdot \langle \mathbf{v} \mathbf{n} \, ds.
$$

This is a generalization of the Newton-Leibniz rule of calculus:

Let $d = 1$, $\Omega = (a, b)$. Then:

- $n_a = (-1)$
- \bullet $n_b = (1)$
- $\bullet \ \nabla \cdot v = v'$

$$
\int_{\Omega} \nabla \cdot \vec{v} \, d\vec{x} = \int_{a}^{b} v'(x) \, dx = v(b) - v(a) = v(a)n_a + v(b)n_b
$$

Species evolution in a domain Ω

Let

- $\cdot \ \Omega$: domain, $(0,T)$: time evolution interval
- $\cdot \; u(\vec{x},t): \Omega \times [0,T] \to \mathbb{R}$ time dependent *local amount of species* (aka species concentration)
- $f(\vec{x},t): \Omega \times [0,T] \rightarrow \mathbb{R}$: species *sources/sinks*
- $\cdot \vec{j}(\vec{x},t): \Omega \times [0,T] \rightarrow \mathbb{R}^d$ vector field of the species flux

Representative ElementaryVolume (REV)

Let $\omega \subset \Omega$: be a *representative elementary volume* (REV) Define averages:

- $\bm{v} \cdot J(t) = \int_{\partial \omega} \vec{j}(\vec{x},t) \cdot \vec{n} \; ds$: flux of species trough $\partial \omega$ at moment t
- $\boldsymbol{u} \cdot \boldsymbol{U}(t) = \int_{\omega} u(\vec{x},t) \ d\vec{x}$ amount of species in ω at moment t
- $\boldsymbol{r} \cdot \boldsymbol{F}(t) = \int_{\omega} f(\vec{x}, t) \ d\vec{x}$: rate of creation/destruction at moment t

Species conservation

Let $(t_0, t_1) \subset (0, T)$. The change of the amount of species in ω during (t_0, t_1) is proportional to the sum of the amount transported through boundary and the amount created/destroyed

$$
U(t_1)-U(t_0)+\int_{t_0}^{t_1}J(t) dt = \int_{t_0}^{t_1}F(t) dt
$$

Using the definitions of U,F,J, we get

$$
\int_{\omega} (u(\langle \mathbf{v}\mathbf{x},t_1\rangle - u(\langle \mathbf{v}\mathbf{x},t_0\rangle) d\langle \mathbf{v}\mathbf{x} + \int_{t_0}^{t_1} \int_{\partial \omega} \langle \mathbf{v} \mathbf{j}(\langle \mathbf{v}\mathbf{x},t\rangle \cdot \langle \mathbf{v}\mathbf{n} ds dt = \int_{t_0}^{t_1} \int_{\omega} f(\langle \mathbf{v}\mathbf{x},t\rangle ds
$$

Gauss' theorem gives

$$
\int_{t_0}^{t_1} \int_{\omega} \partial_t u(\langle \mathbf{v} \mathbf{x}, t \rangle) d\langle \mathbf{v} \mathbf{x} dt + \int_{t_0}^{t_1} \int_{\omega} \nabla \cdot \langle \mathbf{v} \mathbf{j}(\langle \mathbf{v} \mathbf{x}, t \rangle) d\langle \mathbf{v} \mathbf{x} dt = \int_{t_0}^{t_1} \int_{\omega} f(\langle \mathbf{v} \mathbf{x}, t \rangle) ds
$$

Continuity equation

The above is true for all $\omega \subset \Omega$, $(t_0,t_1) \subset (0,T) \Rightarrow$

 $\partial_t u(\forall \mathbf{x}, t) + \nabla \cdot \langle \mathbf{v} \mathbf{j}(\forall \mathbf{x}, t) = f(\forall \mathbf{x}, t) \quad \text{in} \ \Omega \times [0, T]$

- While this sounds obvious, mathematical reasoning about this is more complex
- Whenever one encounters the divergence operator, chances are that it describes a conservation law for certain species. This physical meaning is very concrete and, if possible should be preserved during the process of discretizing PDEs.

Flux expressions

As a rule, species flux is proportional to the negative gradient of the species concentration: $\vec{j}(\vec{x},t) \sim -\vec{\nabla} u(\vec{x},t)$. This corresponds to the direction of steepest descend.

Therefore we set $\vec{j}=-\delta\vec{\nabla}u$, where $\delta>0$ can be constant, space/time dependent or even depend on u . For simplicity, we assume δ to be constant, unless stated otherwise.

Heat conduction

- $\bullet \, u = T$: temperature
- $\cdot \delta = \lambda$: heat conduction coefficient
- \bullet f : heat source
- $\cdot \vec{j} = -\lambda \vec{\nabla} T$: Fourier law

Diffusion of molecules in a given medium (for low

concentrations)

- $\cdot u = c$: concentration
- $\cdot \delta = D$: diffusion coefficient
- \bullet f: species source (e.g due to reactions)
- $\vec{j} = -D\vec{\nabla}c$: Fick's law

Flow in a saturated porous medium:

- $\bullet \, u = p$: pressure
- \bullet $\delta = k$: permeability
- $\cdot \vec{j} = -k \vec{\nabla} p$: Darcy's law

Electrical conduction

- $\cdot u = \varphi$: electric potential
- $\delta = \sigma$: electric conductivity
- $\cdot \vec{j} = -\sigma \vec{\nabla} \varphi \equiv$ current density: Ohms's law

Electrostatics in a constant magnetic field:

- $\cdot u = \varphi$: electric potential
- $\cdot \delta = \varepsilon$: dielectric permittivity
- $\cdot \vec{E} = \vec{\nabla}\phi$: electric field
- $\cdot \vec{j} = \vec{D} = \varepsilon \vec{E} = \varepsilon \vec{\nabla} \varphi$: electric displacement field: *Gauss's Law*
- $f = \rho$: charge density

Second order partial differential equations (PDEs)

Combine continuity equation with flux expression:

$$
\partial_t u - \nabla \cdot (\delta \nabla u) = f.
$$

This type of PDEs is called *parabolic*.

Assuming stationarity - i.e. independence of time results in $\partial_t u = 0$ and the *elliptic* PDE

$$
-\nabla\cdot(\delta\nabla u)=f.
$$

Boundary conditions

So far, we cared about the species balance of an REV in the interior of the domain.How about the species balance between Ω and its exterior ? This is described by *boundary conditions*.

Assume $\partial\Omega = \bigcup_{i=1}^{N_\Gamma}\Gamma_i$ is the union of a finite number of non-intersecting subsets Γ_i which are locally Lipschitz.

Define boundary conditions on each of Γ_i

Dirichlet boundary conditions

Let $g_i: \Gamma_i \to \mathbb{R}$.

$$
u(\vec{x},t) = g_i(\vec{x},t) \quad \text{for } \vec{x} \in \Gamma_i
$$

- fixed solution at the boundary
- also called *boundary condition of first kind*
- called *homogeneous* for $g_i = 0$

Neumann boundary conditions

Let $g_i: \Gamma_i \to \mathbb{R}$.

$$
-\backslash \mathbf{vj}(\vec{x},t)\cdot\vec{n}=g_i(\vec{x},t) \quad \text{for } \vec{x}\in\Gamma_i
$$

- fixed boundary normal flux
- also called *boundary condition of second kind*
- called *homogeneous* for $g_i = 0$

Robin boundary conditions

let $\alpha_i > 0, g_i : \Gamma_i \to \mathbb{R}$

$$
-\backslash \textbf{vj}(\backslash \textbf{vx},t) \cdot \vec{n} + \alpha_i(\vec{x},t) u(\vec{x},t) = g_i(\vec{x},t) \quad \text{for } \vec{x} \in \Gamma_i
$$

- Boundary flux proportional to solution
- also called *third kind boundary condition*

Generalizations

- $\bullet \ \delta$ may depend on \vec{x}, u , $|\vec{\nabla}u| \ldots \Rightarrow$ equations become nonlinear
- Coefficients can depend on other processes
	- o temperature can influence conductvity
	- source terms can describe chemical reactions between different species
	- o chemical reactions can generate/consume heat
	- Electric current generates heat (``Joule heating'')
	- \circ ...

 \Rightarrow coupled PDEs

- Convective terms: $\vec{j} = -\delta \vec{\nabla} u + u \vec{v}$ where \vec{v} is a convective velocity
- PDEs for vector unknowns
	- \circ Momentum balance \Rightarrow Navier-Stokes equations for fluid dynamics
	- Elasticity
	- Maxwell's electromagnetic field equations
