Other lattice models for random growth

- Dielectric breakdown models (DBM)
- Internal diffusion-limited aggregation (IDLA)
- First passage percolation (FPP)
- Interface models: ballistic deposition, corner growth model, etc.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 シののや

What do we know about lattice models for random growth?

Not much!

- DLA first formulated in 1981 by Witten and Sander.
- Original paper has almost 7,000 citations.
- Only one rigorous result in over 40 years: At time t DLA is contained in a ball of radius $t^{2/3}$ (Kesten, 1987).
- No proof (or even convincing explanation) that DLA does not converge to a ball.
- Main open problems:
 - Existence of universal limit.
 - Growth rate of the cluster.
 - Structure of the limiting set (e.g. fractal dimension).

DLA cluster with 145,199,976 particles

Simulation by B.Grebenkov and D.Beliaev

Amanda Turner Department of Statistics University of Leeds, UK

Off-lattice DLA

Ball shaped particles perform BM (from infinity) until they attach to the aggregate.

Amanda Turner Department of Statistics University of Leeds, UK

Harmonic measure

- The attachment point is distributed according to harmonic measure on the cluster boundary (from infinity).
- By conformal invariance of BM, harmonic measure is conformally invariant.
- An algorithm for sampling a boundary point of a set A: Let D_0 denote the exterior unit disk in the complex plane \mathbb{C} and let $\Phi : D_0 \to A^c$ be conformal. Choose a point $y \in \partial D_0$ uniformly. Then take $\Phi(y)$.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 シののや

But how do you find Φ?

Conformal mapping representation of a slit-shaped particle

Let *P* denote the slit $[1, 1 + \delta]$ in the complex plane.

There exists a unique conformal mapping $F: D_0 \to D_0 \setminus P$ that fixes ∞ in the sense that

$${\sf F}(z)=e^{c}z+O(1)$$
 as $|z| o\infty,$

for some c>0, the (log of the) capacity, which satisfies $e^c=1+rac{\delta^2}{4(1+\delta)}.$

Amanda Turner Department of Statistics University of Leeds, UK

Conformal mapping representation of a cluster

Suppose P₁, P₂,... is a sequence of particles, where P_n has capacity c_n (or length δ_n) and attachment angle Θ_n, n = 1, 2, Let F_n be the particle map corresponding to P_n.

• Set
$$\Phi_0(z) = z$$

- Recursively define $\Phi_n(z) = \Phi_{n-1} \circ F_n(z)$, for n = 1, 2, ...
- This generates a sequence of conformal maps $\Phi_n : D_0 \to K_n^c$, where $K_{n-1} \subset K_n$ are growing compact sets, which we call clusters.

Parameter choices for physical models

- By varying the sequences {Θ_n} and {c_n}, it is possible to describe a wide class of growth models.
- For biological growth (Eden model)

$$\mathbb{P}(\Theta_n \in (a,b)) \propto \int_a^b |\Phi_{n-1}'(e^{i heta})| d heta$$

and

$$c_n \approx c |\Phi'_{n-1}(e^{i\Theta_n})|^{-2}$$

■ For DLA, *c_n* is as above and

$$\mathbb{P}(\Theta_n \in (a,b)) = \mathbb{P}(\Phi_{n-1}^{-1}(B_{\tau}) \in (a,b)) \propto (b-a)$$

where B_t is Brownian motion started from ∞ and τ is the hitting time of the cluster K_{n-1} .

Amanda Turner Department of Statistics University of Leeds, UK

Aggregate Loewner Evolution, $ALE(\alpha, \eta, \sigma)$

• Θ_n distributed $\propto |\Phi'_{n-1}(e^{\sigma+i\theta})|^{-\eta}d\theta;$ $c_n = c|\Phi'_{n-1}(e^{\sigma+i\Theta_n})|^{-\alpha}.$

Amanda Turner Department of Statistics University of Leeds, UK

Regularization for ALE

- Even after the arrival of a single slit particle, the map $\theta \mapsto |\Phi'_n(e^{i\theta})|$ is badly behaved and takes the values 0 and ∞ .
- For some values of η,

$$\int_{-\pi}^{\pi} |\Phi_{n-1}'(e^{i\theta})|^{-\eta} d\theta = \infty,$$

so regularization is necessary to even define the measure.

• A solution is to let Θ_n have distribution

$$\propto |\Phi_{n-1}'(e^{\sigma+i heta})|^{-\eta}d heta$$

for $\sigma > 0$ and take the limit $\sigma \rightarrow 0$.

• Models are very sensitive to the rate at which $\sigma \rightarrow 0$. Can be argued that $\sigma \sim c^{1/2}$ is natural from a physical point of view.

Amanda Turner Department of Statistics University of Leeds, UK

Phase transition

Open Problem:

Does ALE(α, η, σ) exhibit a phase transition from disks to non-disks along the line $\alpha + \eta = 1$ (for 'broad' choices of the regularization parameter σ)?

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 シののや

- Longstanding conjectures:
 - $HL(\alpha)$ has a phase transition at $\alpha = 1$.
 - **DBM**(η) has a phase transition at $\eta = 0$.

Amanda Turner Department of Statistics University of Leeds, UK

Previous results: HL(0)

Much of the previous work relates to HL(0) as particle maps are i.i.d. so the model is mathematically the most tractable.

- Norris and Turner (2012):
 - small-particle scaling limit of HL(0) is a growing disk: $\Phi_n(z) \approx e^{cn}z$
 - branching structure is related to the Brownian web
 - expected size of the n^{th} particle is roughly $\delta \exp cn$, so HL(0) is "unphysical".
- Silvestri (2017): fluctuations converge to a log-correlated Fractional Gaussian Field.

HL(0)-like model variants

- Sola, Turner, Viklund (2012): Anisotropic HL(0)
- Berestycki and Silvestri (2021): Constrained HL(0)
- Berger, Turner, Procaccia (2021): Stationary HL(0)

イロト イボト イヨト イヨト

Amanda Turner Department of Statistics University of Leeds, UK

$HL(\alpha)$ for $\alpha \neq 0$

All results for HL(α) with $\alpha \neq 0$ require some kind of regularization.

- Rohde and Zinsmeister (2005) obtained estimates on the dimension of scaling limits for a regularized version of HL(α).
- Sola, T., Viklund (2015) showed small-particle scaling limit of regularized HL(α) is a growing disk for all α provided regularization parameter σ is large enough.
- Liddle and T. (2021) obtained disk-limits and fluctuation results for $HL(\alpha)$ under capacity rescaling, regularized at ∞ , when $\alpha \in (0, 2)$.

ALE family in the singular regime

- Sola, T., Viklund (2019) showed scaling limit of ALE(α, η, σ) is a single slit if α ≥ 0 and η > 1 when using slit particles, provided σ is very small.
- Higgs (2021) showed scaling limit of ALE(0, η, σ) converges to a SLE₄ for η < -2 when using slit particles, provided σ is very small. Other SLE_κ's with κ > 4 can be obtained by using different particle shapes.

イロト 不同 トイヨト イヨト

Amanda Turner Department of Statistics University of Leeds, UK

ALE family in the disk-regime

Norris, Turner, Silvestri (2022 and 2024)

• Scaling limit: For all $\alpha + \eta \leq 1$, provided $\sigma \gg c^{1/2}$ as $c \to 0$ ($\sigma \gg c^{1/3}$ when $\alpha + \eta = 1$),

$$\Phi_n(z) \approx (1 + \alpha cn)^{1/\alpha} z.$$

• Fluctuations: Set $\mathcal{F}_n^{(c)}(z) = c^{-1/2} \left((1 + \alpha cn)^{-1/\alpha} \Phi_n(z) - z \right)$. Then $\mathcal{F}_{\lfloor t/c \rfloor}^{(c)}(z) \to \mathcal{F}_t(z)$ where $\dot{\tau}(z) = \frac{1}{2} \left((1 - (z + z)) - \tau'(z) - \tau(z) + \sqrt{2}c(z) \right)$

$$\dot{\mathcal{F}}_t(z) = \frac{1}{1+\alpha t} \left(\left(1-(\alpha+\eta)\right) z \mathcal{F}'_t(z) - \mathcal{F}_t(z) + \sqrt{2}\xi_t(z) \right).$$

Here $\xi_t(z)$ is complex space-time white noise on the circle, analytically continued to the exterior unit disk.

Amanda Turner Department of Statistics University of Leeds, UK

Fluctuations for ALE(α, η, σ) when $\alpha + \eta \leq 1$

Specifically

$$\mathcal{F}_t(z) = \sum_{m=0}^{\infty} (A_t^m + iB_t^m) z^{-m}$$

where

$$dA_t^m = -\frac{(m(1-\alpha-\eta)+1)A_t^m}{1+\alpha t}dt + \frac{\sqrt{2}}{1+\alpha t}d\beta_t^m$$

$$dB_t^m = -\frac{(m(1-\alpha-\eta)+1)B_t^m}{1+\alpha t}dt + \frac{\sqrt{2}}{1+\alpha t}d\beta_t^{\prime m}.$$

Here $\beta_t^m, \beta_t^{\prime m}$ are i.i.d. Brownian motions for $m = 0, 1, \ldots$, so

$$A_t^m, B_t^m \sim \mathcal{N}\left(0, \frac{1 - e^{-2(m(1 - \alpha - \eta) + 1)\tau_t}}{m(1 - \alpha - \eta) + 1}\right).$$

Amanda Turner Department of Statistics University of Leeds, UK

Remarks

- The map $z \mapsto \mathcal{F}_t(z)$ is determined (by analytic extension) by the boundary process $\theta \mapsto \mathcal{F}_t(e^{i\theta})$.
- When $\alpha = \eta = 0$, these boundary fluctuations are the same as for internal diffusion limited aggregation (IDLA).
- As $t \to \infty$, $\mathcal{F}_t(e^{i\theta})$ converges to a Gaussian field.
 - When α + η = 0, 𝓕_∞(e^{iθ}) is known as the augmented Gaussian Free Field.
 - When $\alpha + \eta < 1$, $\operatorname{Cov} \left(\mathcal{F}_{\infty}(e^{ix}), \mathcal{F}_{\infty}(e^{iy}) \right) \asymp \log |x y|$.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 シののや

• When $\alpha + \eta = 1$, $\mathcal{F}_{\infty}(e^{i\theta})$ is complex white noise.
