Mutual exclusivity / co-occurrence

Colorectal Adenocarcinoma (TCGA, Nature 2012)

KRAS-BRAF: mutational exclusive
odds-ratio: 0.22, $p < 0.001$ (Fisher's exact test)

KRAS-PIK3CA: co-occurrent
odds-ratio: 2.70, $p < 0.001$ (Fisher's exact test)

Statistical Power!

Assume two genes are mutually exclusive
odds-ratio: 1/4; each gene mutated in 3% of cases

How many samples to obtain a p-value of 0.01?

9924 samples with Fisher's exact test
multiple testing not yet considered!!!

**What is the order of the genes
in the pathway?**

Systematic mapping of multivariate genetic interactions via RNAi

all pairwise knock-downs of

image-based readout

1367 genes x 72 genes

Interventions

Phenotypes

with Michael Boutros, DKFZ
Fischer*, Sandmann*, Horn*, Billmann*, eLife, 2015 (Directional Interactions)
Horn*, Sandmann*, Fischer*, Nat. Methods, 2011

Single knock down phenotypes

ida is member of the APC

- number cells
- mitotic index
- nuclear area
- eccentricity

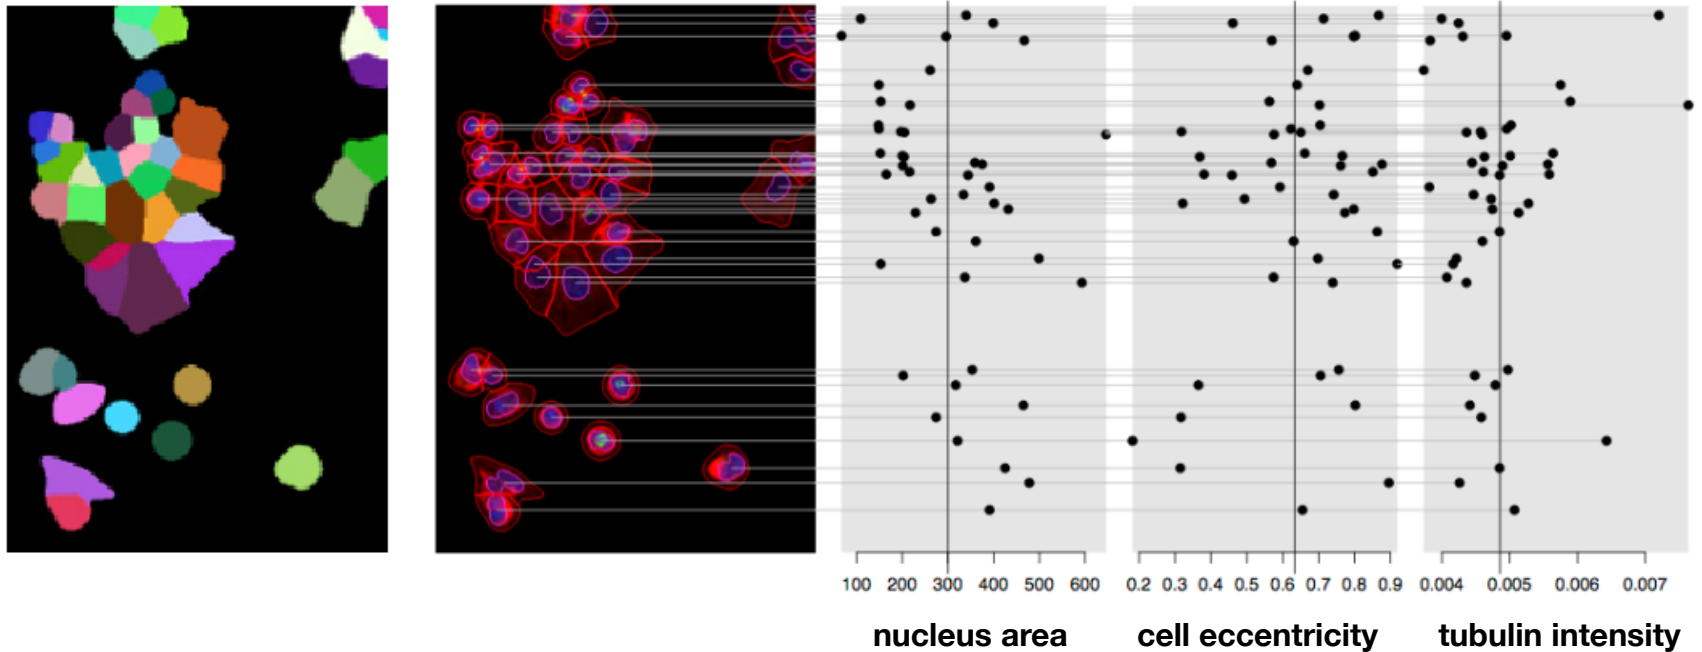

Image segmentation and feature extraction

- features: number cells, ratio of mitotic cells, local cell density, radius, area, shape, texture (Haralick)
- **21 non-redundant features selected**

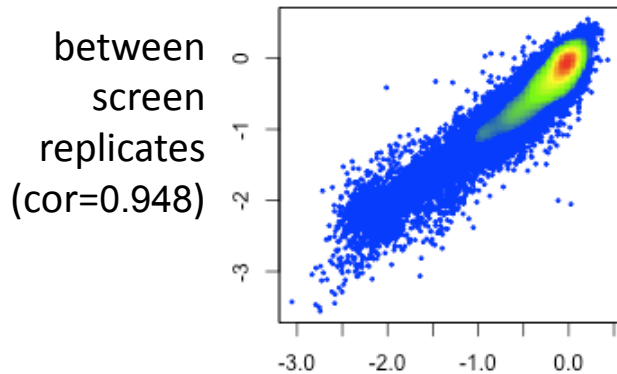

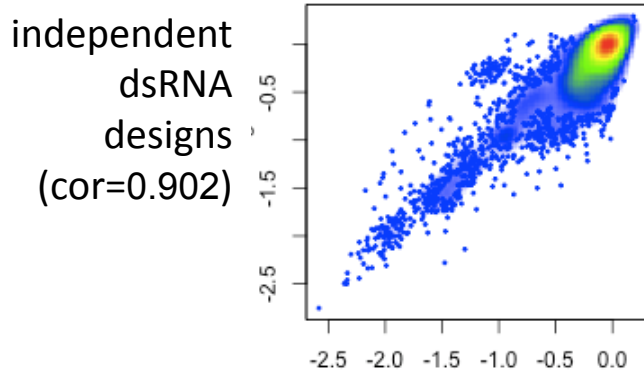

Bioconductor
OPEN SOURCE SOFTWARE FOR BIOINFORMATICS

packages EBImage / imageHTS / rhdf5

(Laufer*, Fischer*, Nat. Methods, 2013)

Quality control and normalization

Quality control:
Filter irreproducible data (irreproducible features, off-target effects)

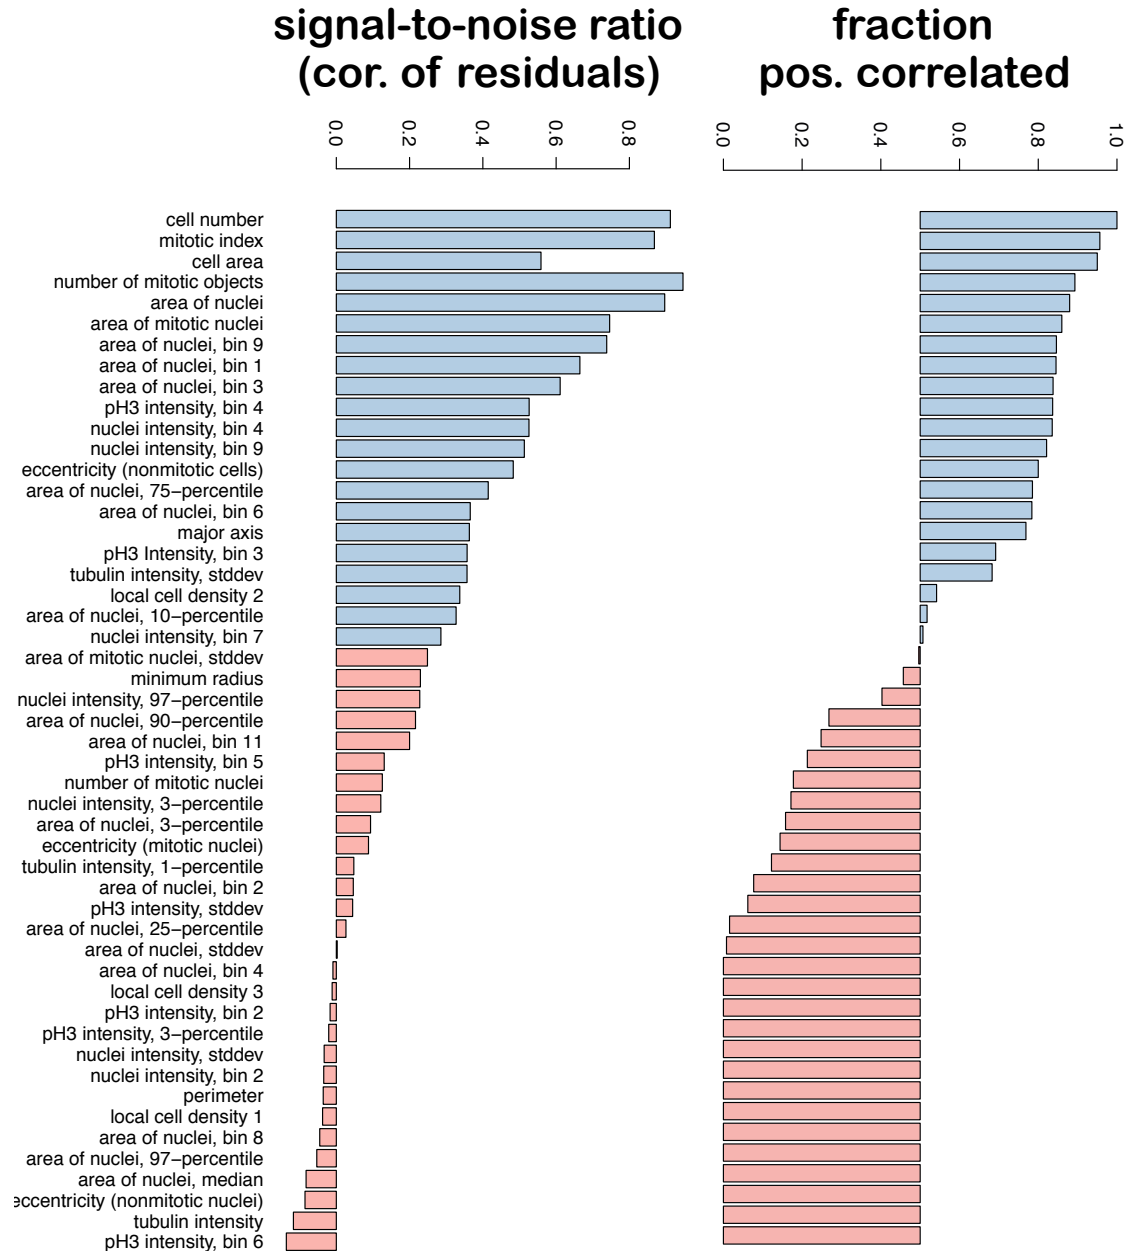

Normalize for known technical artefacts:
spatial effects, time effects, ...

21 non-redundant features

Selection procedure:

- Fit a linear model for each feature as a function of the previously selected features
- Select the feature among all remaining ones with highest correlation of residuals between replicates
- Stop criterium: equal proportion of pos. and neg. residual correlations

Raw data cube

1293 target genes

x 72 query genes

x 21 feature

(statistical) genetic interactions

- For many phenotypes, the main effects (single gene) are multiplicative for non interacting genes i, j : $d_{ij} = \varpi \cdot \mu_i \cdot \mu_j$ R.A. Fisher, 1918

- Additive on logarithmic scale

$$\log d_{ijk} = w + m_i + m'_j + g_{ij} + \varepsilon_{ijk}$$

measurement
(nr cells, growth rate, ...)

effect of control

main effect of dsRNA i

main effect of dsRNA j

interaction term
0, for non interacting genes
 $\neq 0$, for interacting genes

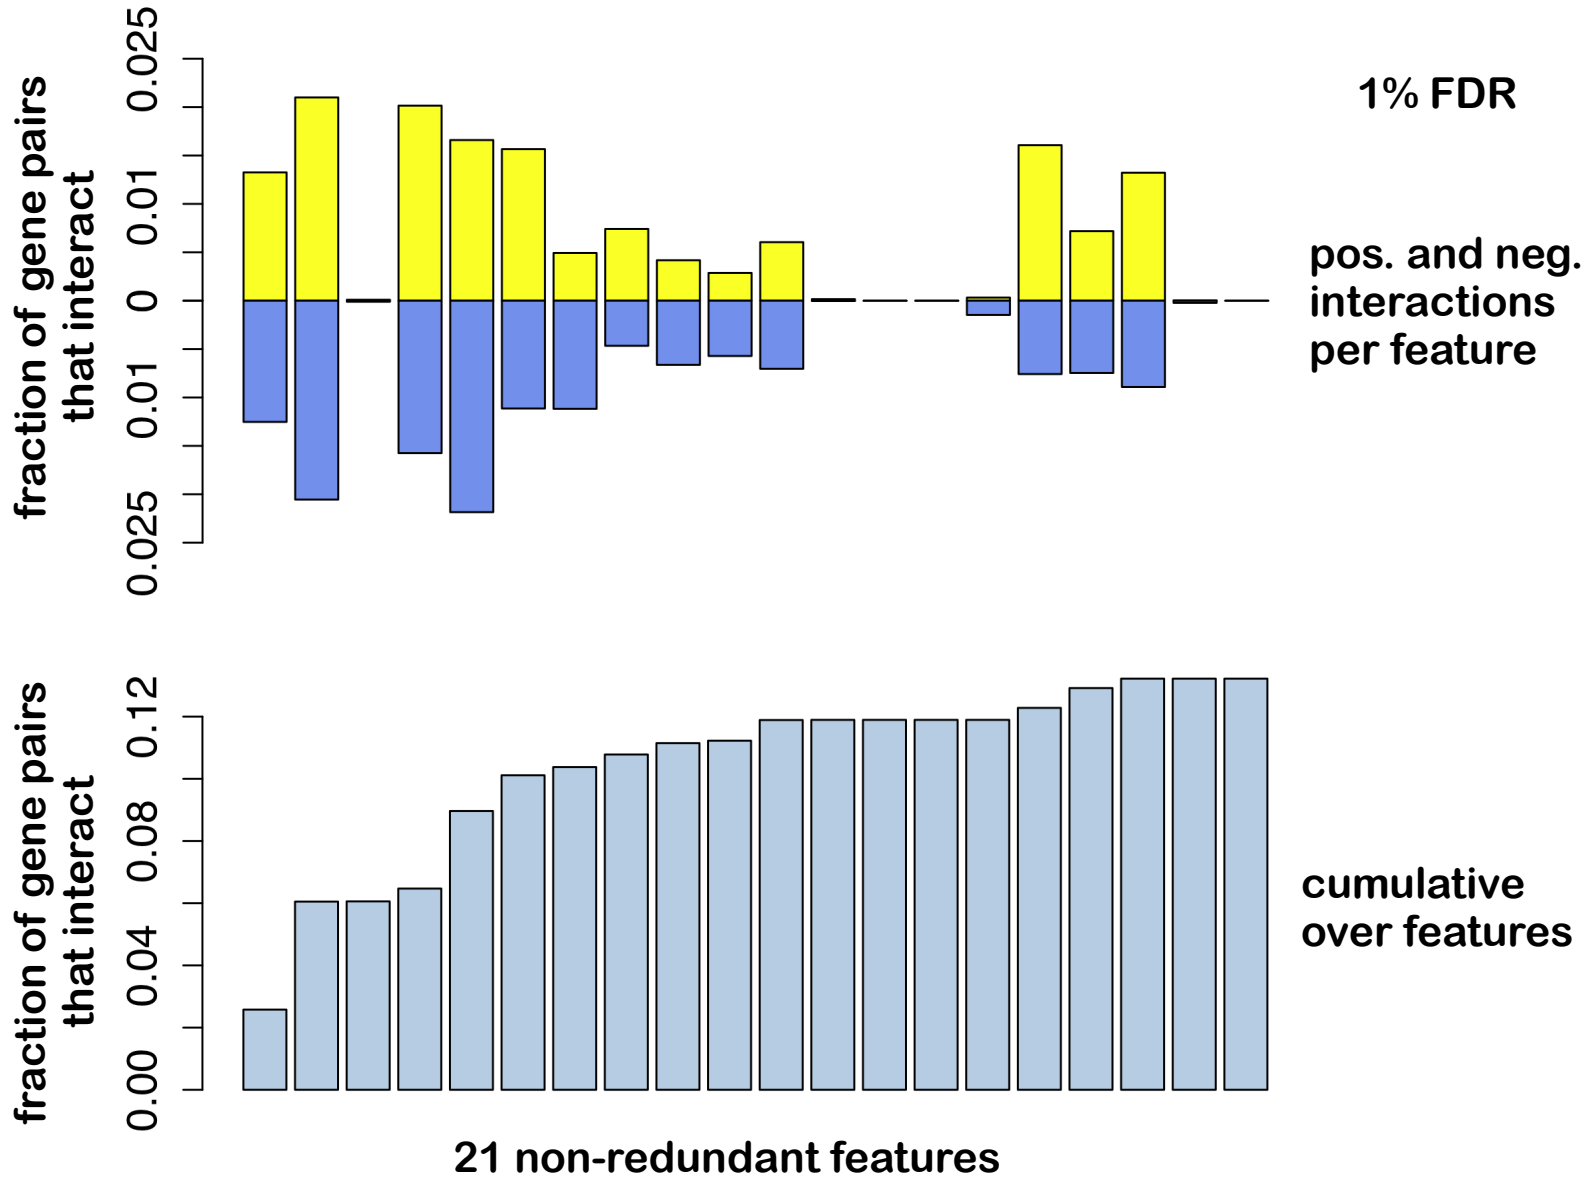

error term

- Estimation of main effects (assume that interactions are rare)

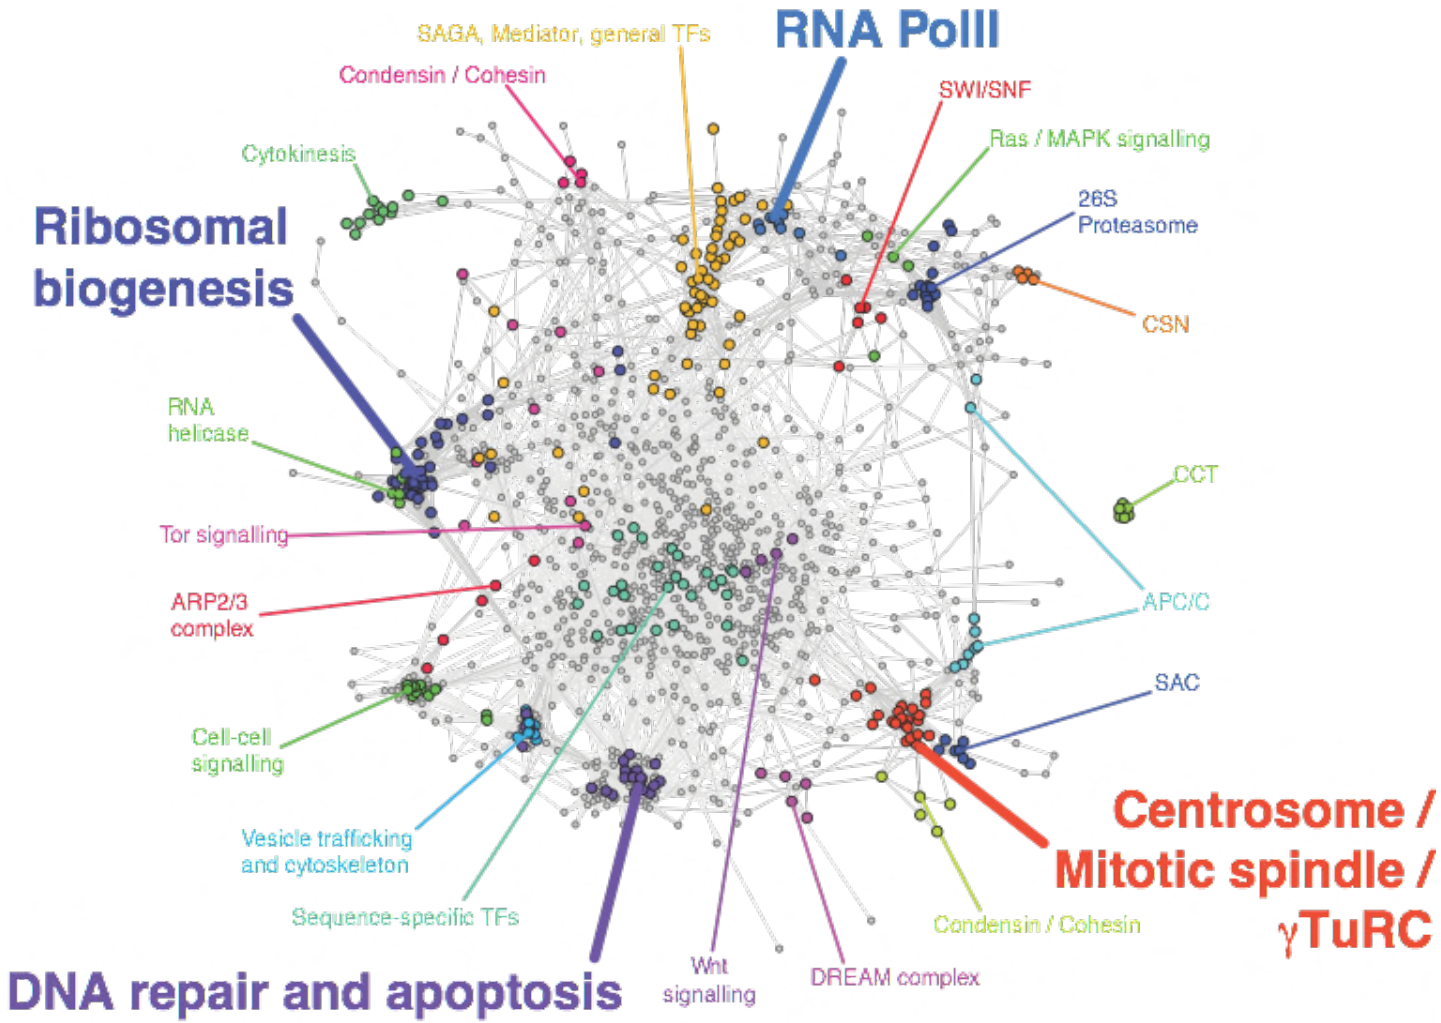

$$(\hat{m}, \hat{m}') = \arg \min_{m, m'} \sum_{i, j} \left\| \log d_{ij} - w - m_i - m_j \right\|_1$$

- Detect Genetic Interactions: Compare $\log d_{ijk}$ to $w - \hat{m}_i - \hat{m}_j$ (t-test)

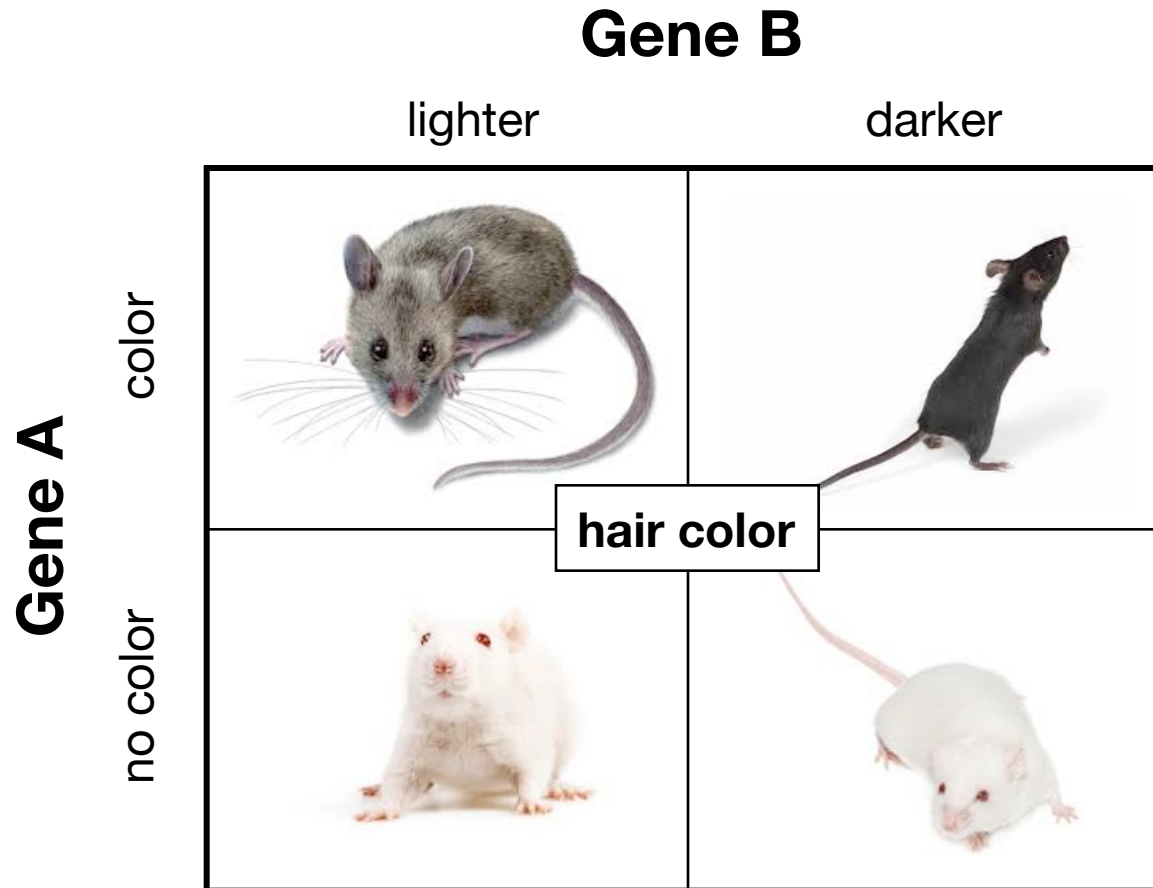

Number of interactions

Functional prediction from large-scale image-based genetic interaction screens

Epistasis

A is epistatic to B

Directional, epistatic interactions

Directional, epistatic interactions

Directional, epistatic interactions

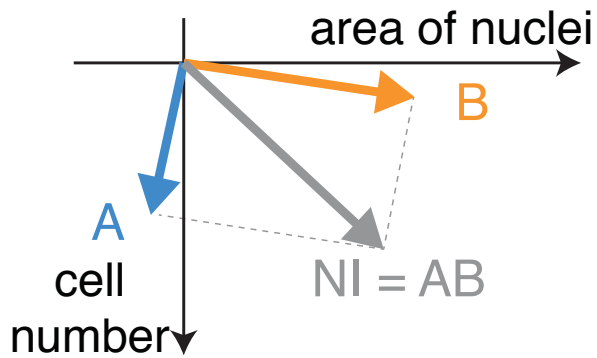

Directional, epistatic interactions

Directional, epistatic interactions

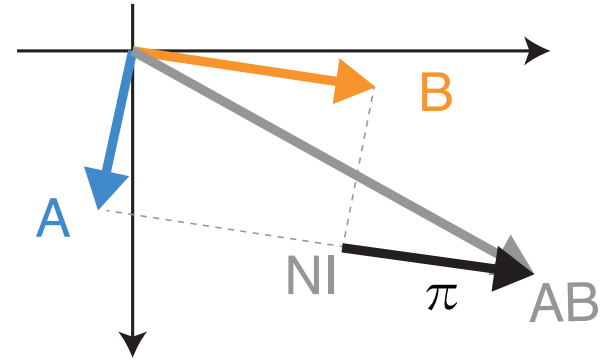

A and B non-interacting

A → B

A ⊣ B

B → A

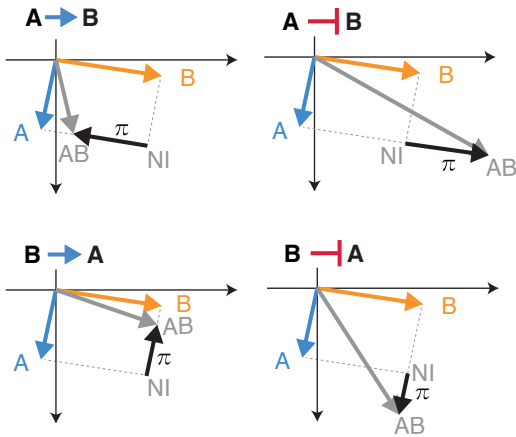

B ⊣ A

Requires multiple phenotypes

Special cases

Directional interactions

No direction detectable

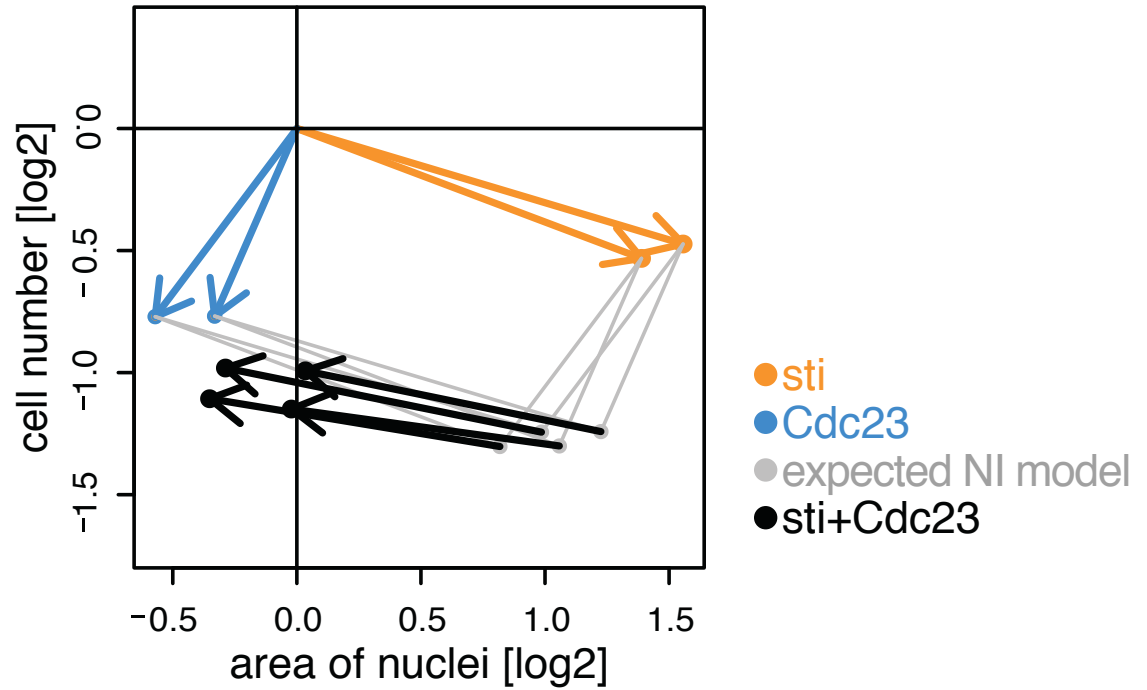

Mixed Epistasis?

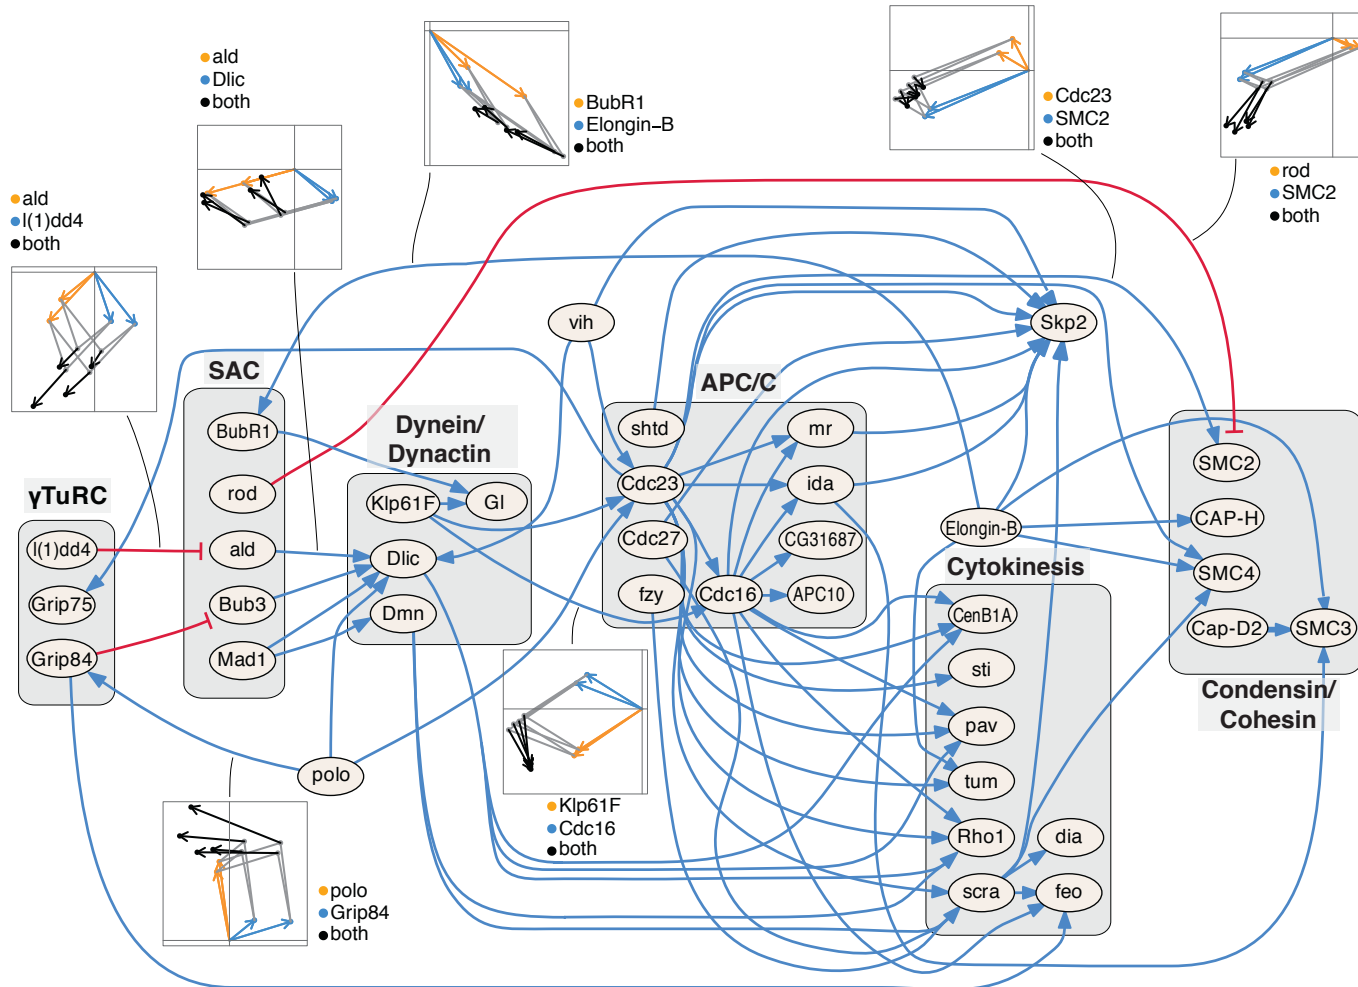

protein complexes

sti depends on cdc23

Directional interactions in mitosis

Observed directional interactions

→ activating (alleviating)
⊥ inhibiting (aggravating)

SWI/SNF interacts with Ras signaling

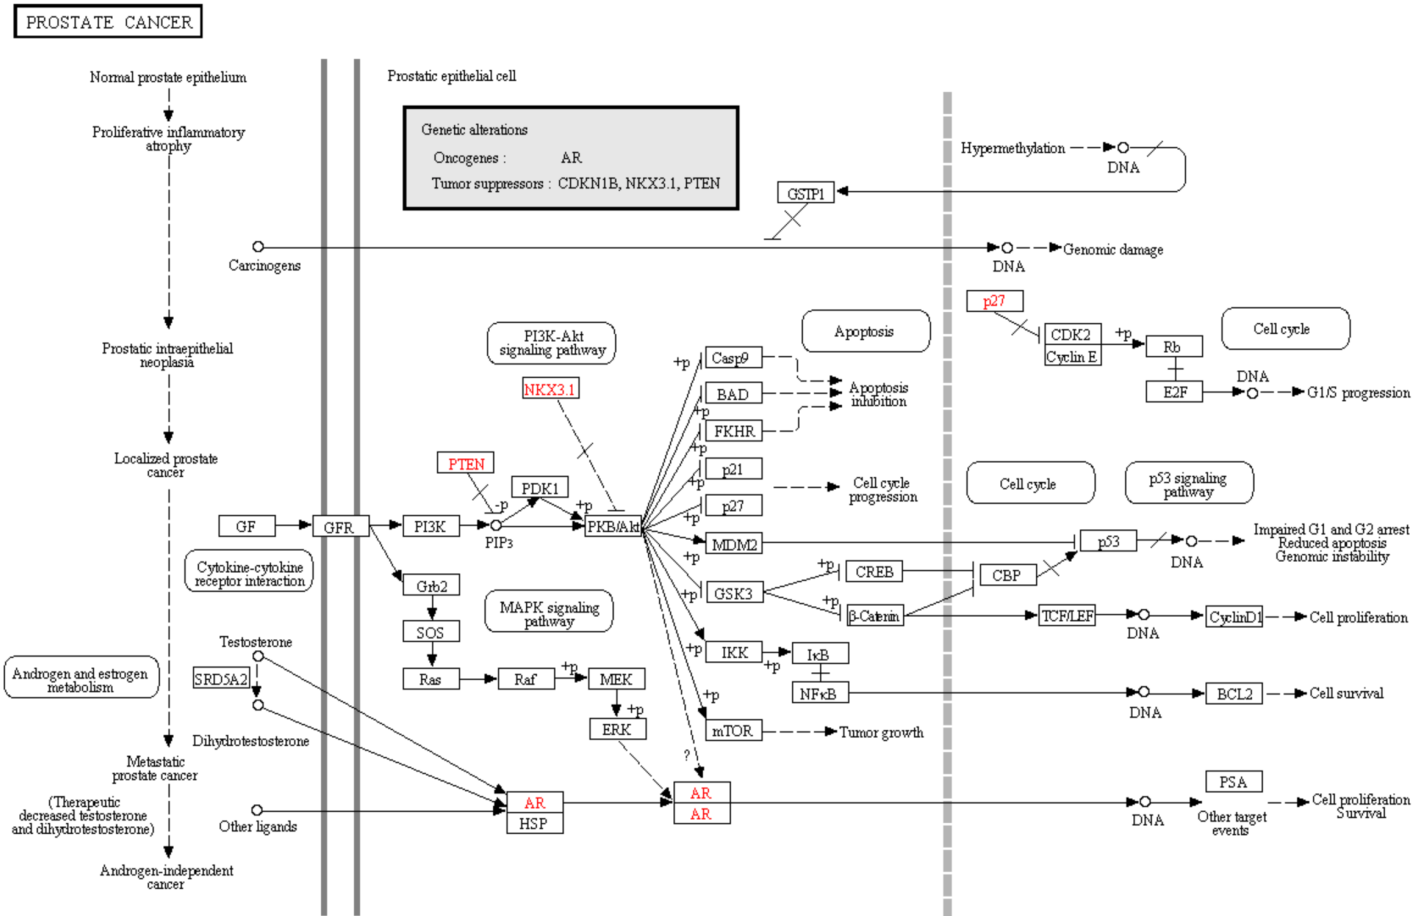

Control
+/+

sev-Ras^{v12/+}

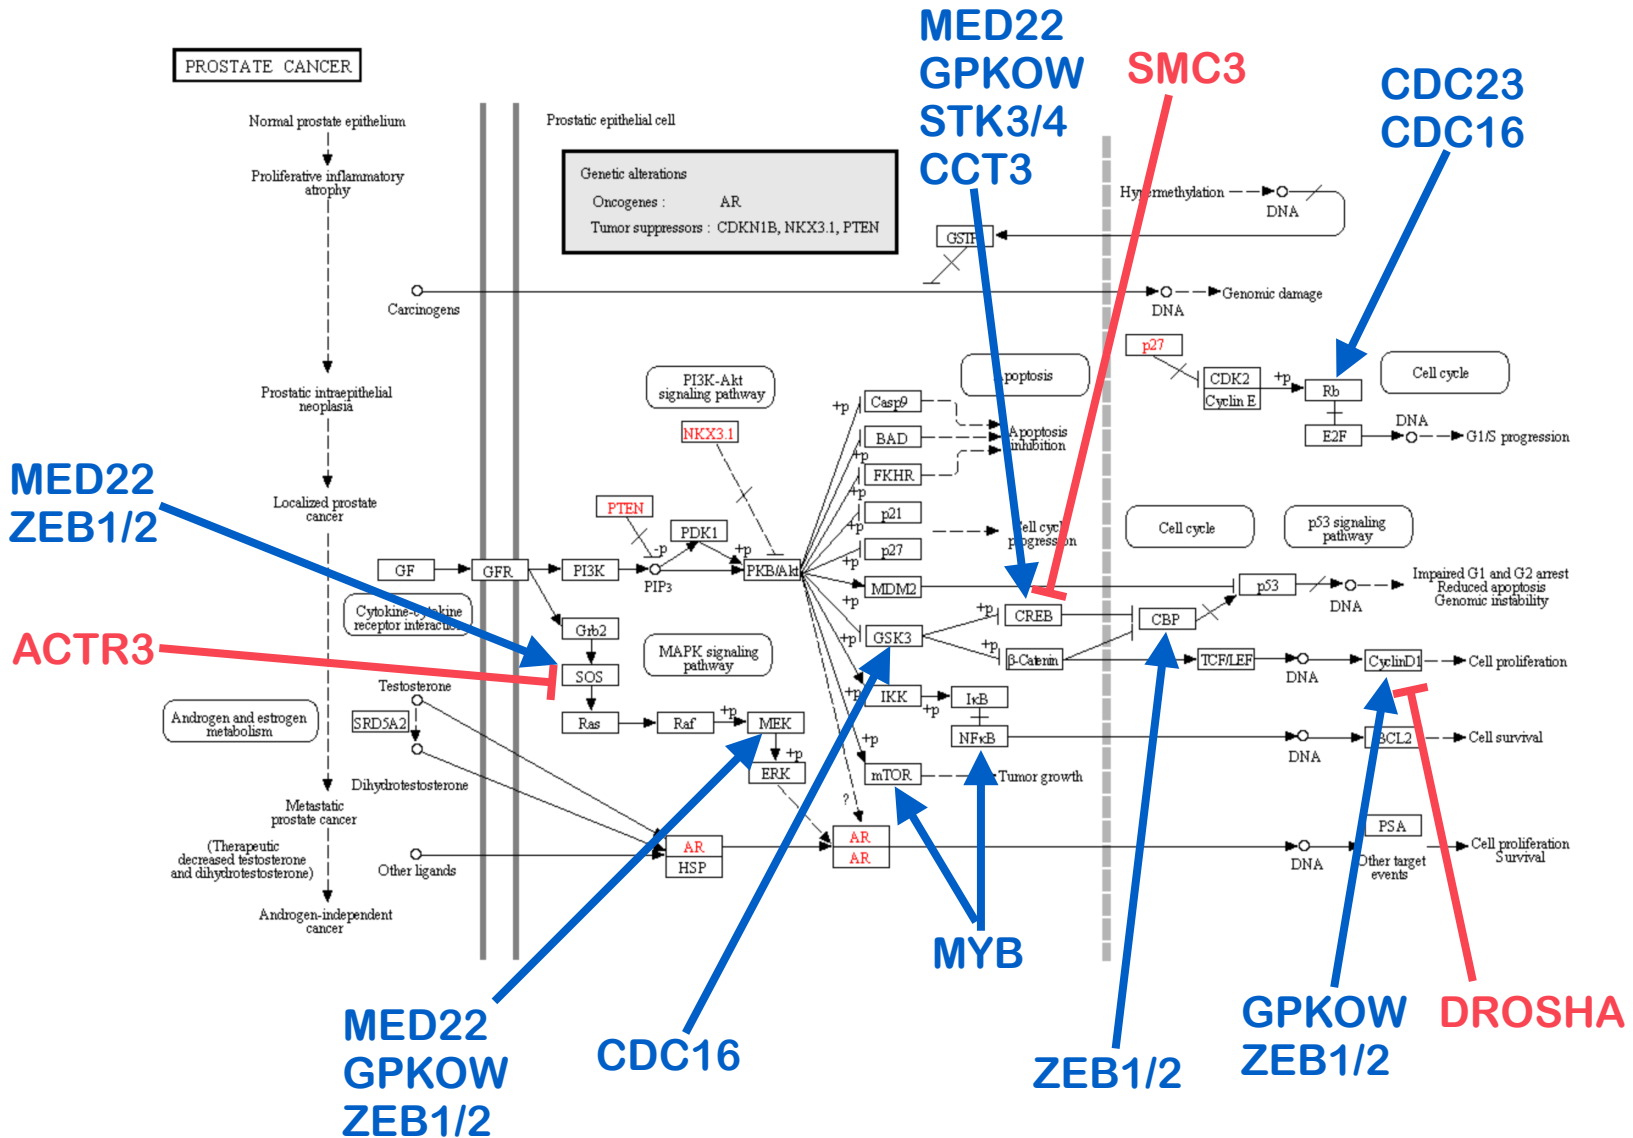

*sev-Ras^{v12/+}
osa²*

KEGG Prostate Cancer Pathway

KEGG Prostate Cancer Pathway

Outlook

3D Organoids to model environment

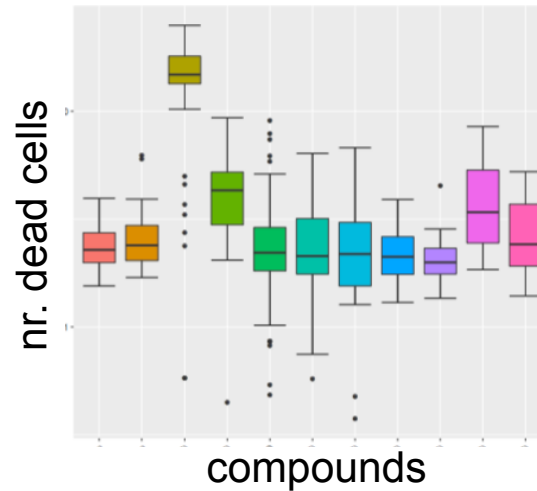

new challenge in image analysis

Deep learning for organoid detection and feature extraction

drug-sensitivity screens with patient cells

test treatment outcome in vitro

models to predict treatment outcome from genomic data

knockdown screens in drug-resistant cells

new combinatorial drug treatments

overcome acquired drug-resistance
